

◆ Architect 2.0: proposed production architecture

BLUEPRINT / REV 01

● **What the shape buys a builder**

- Per stage meters at the gateway are where a cost estimate comes from, before the build rather than after it
- A trace per step is what answers "Why did it do that?" without reading a log
- A checkpoint commit per step, so a bad step is one revert rather than a rebuild

● **Proposed, not built**

- This is the target architecture, written up in docs/ARCHITECTURE.md
- The demo implements sign in, per user Postgres rows and live decision model calls
- What runs today is the separate system architecture diagram

● **Boundaries that do real work**

- Secrets reach the sandbox at run time and never enter model context
- One sandbox per build with an egress allowlist, so a generated command cannot reach the platform
- Deployed apps hold no provider keys: they call agents through the runtime proxy
